Abstract
B-cell chronic lymphocytic leukemia (B-CLL) patients expressing unmutated immunoglobulin heavy variable regions (IGHV6) use the IGHV1-69 B cell receptor (BCR) in 25% of cases. Since HIV-1 envelope gp41 antibodies also frequently use IGHV1-69 gene segments, we hypothesized that IGHV1-69 B-CLL precursors may contribute to the gp41 B cell response during HIV-1 infection. To test this hypothesis, we rescued 5 IGHV1-69 unmutated antibodies as heterohybridoma IgM paraproteins and as recombinant IgG1 antibodies from B-CLL patients, determined their antigenic specificities and analyzed BCR sequences. IGHV1-69 B-CLL antibodies were enriched for reactivity with HIV-1 envelope gp41, influenza, hepatitis C virus E2 protein and intestinal commensal bacteria. These IGHV1-69 B-CLL antibodies preferentially used IGHD3 and IGHJ6 gene segments and had long heavy chain complementary determining region 3s (HCDR3s) (≥21 aa). IGHV1-69 B-CLL BCRs exhibited a phenylalanine at position 54 (F54) of the HCDR2 as do rare HIV-1 gp41 and influenza hemagglutinin stem neutralizing antibodies, while IGHV1-69 gp41 antibodies induced by HIV-1 infection predominantly used leucine (L54) allotypic variants. These results demonstrate that the B-CLL cell population is an expansion of members of the innate polyreactive B cell repertoire with reactivity to a number of infectious agent antigens including intestinal commensal bacteria. The B-CLL IGHV1-69 B cell usage of F54 allelic variants strongly suggests that IGHV1-69 B-CLL antibodies derive from a restricted B cell pool that also produces rare HIV-1 gp41 and influenza hemagglutinin stem antibodies.

Introduction
The initial B cell responses to HIV-1 envelope (Env) gp41 are non-neutralizing [1] and are polyreactive with human intestinal commensal bacterial antigens [2]. Env gp41 antibodies that arise following HIV-1 transmission do not select virus escape mutants and therefore exert no anti-viral immune pressure [1]. We have recently demonstrated that gp41-reactive B cells can be isolated prior to infection in HIV-1-infected humans and that HIV-1 activates preexisting B cells that are cross-reactive with gp41 and non-HIV-1 antigens including microbial antigens [2]. However, the pool of B cells from which the initial HIV-1 Env B cell response is derived is not known.

B chronic lymphocytic leukemia (B-CLL) is a clonal expansion of CD5+ B lymphocytes frequently associated with unmutated B cell receptors (BCRs) [3]. B-CLL cells with unmutated immunoglobulin heavy variable regions (IGHV) (unmutated CLL, U-CLL) show a preferential usage of IGHV1-69 gene segment (~25%) and frequently have BCRs that are polyreactive and autoreactive despite dramatic structural restrictions [4–10]. The cellular origin of B-CLL cells has been an area of considerable debate. For example, it has been proposed that B-CLL cells derive from human B-1-like cells, marginal zone (MZ) innate B cells, or transitional B cells, based on cell surface phenotype and molecular and functional characteristics [11]. In this regard, recent studies identified a human equivalent of murine B-1 cells (CD20+, CD27+, CD43−, CD70−) [12] and circulating CD5+ human B cells [13] as the precursors of CLL B cells. It has also been proposed that B-CLL cells with BCR stereotypy could derive from B-1-like...
progenitor cells adapted to particular antigenic challenges while B-CLL cells with heterogeneous BCRs could derive from conventional B cells [14]. In addition, anti-viral innate antibodies have been reported to be derived from B-1/MZ B cells [15–17].

The IGHV1-69 BCR allelic variants expressed in B-CLL cells predominantly use a phenylalanine at position 54 (F54) of the heavy chain complementarity determining region 2 (HCDR2) [18,19] and the estimated global frequency of F54 is 60% [20]. Interestingly, influenza antibodies (e.g. CR6261, F10, FE33, and 1009-3B05) [21–24] and HIV-1 antibodies (e.g. D5, HK20, and Fab 8066) [25–27] that bind to the hemagglutinin stem or HIV-1 gp41 regions, respectively, have been reported to use F54 IGHV1-69 allelic variants, and in the case of influenza antibodies, such F54 antibodies are broadly neutralizing [21–24]. Thus, in allele variants showed a common binding mode to gp41 heptad repeat (HR)-1 coiled-coil hydrophobic pocket [25–27]. Thus, in this study we hypothesized that IGHV1-69 B-CLL precursors may contribute to the gp41 B cell response during HIV-1 infection. We identified B-CLL IGHV1-69 antibodies cross-reacting with viral and commensal bacterial antigens, evaluated their association with clinical outcome of B-CLL patients, and compared the immunoglobulin gene characteristics with those of HIV-1 gp41 antibodies isolated from HIV-1 infection.

**Methods**

**Ethics statement**

Specimens collected from B-CLL patients were obtained under an Institutional Review Board (IRB) approved protocol at The Feinstein Institute for Medical Research, North Shore – LIJ Health System, Manhasset, NY and were part of The Feinstein’s Center for CLL Research Biorepository. The research was conducted according to the principles expressed in the Declaration of Helsinki. Written informed consent was obtained from all subjects.

De-identified PBMCs from B-CLL patients not collected for the purpose of this research were obtained from The Feinstein’s Center for CLL Research Biorepository under a Duke IRB exemption and fully executed material transfer agreement. Normal donors were collected under a Duke IRB approved protocol. The research was conducted according to the principles expressed in the Declaration of Helsinki. Written informed consent was obtained from all subjects.

The Duke University Health System Institutional Review Board for Clinical Investigations (DUHS IRB), is duly constituted, fulfilling all requirements for diversity, and has written procedures for initial and continuing review of human research protocols. The DUHS IRB complies with all U.S. regulatory requirements related to the protection of human research participants. Specifically, the DUHS IRB complies with 45CFR46, 21CFR50, 21CFR56, 21CFR312, 21CFR812, and 45CFR164.508–514. In addition, the DUHS IRB complies with the Guidelines of the International Conference on Harmonization to the extent required by the U.S. Food and Drug Administration.

**Cell culture**

Epstein-Barr virus (EBV)-stimulation of patient peripheral blood mononuclear cells (PBMCs) and generation of B-CLL hetero-hybridoma cell lines have been described previously [28]. We stimulated PBMCs from 38 B-CLL patients (33 IGHV1-69 and 25 IGHV1-69) with EBV in the presence of a Toll-like receptor 9 agonist ODN2006 (12.5 μg/ml; Invivogen) and cyclosorpin A (0.5 μg/ml), and cultured the cells in the presence of feeder cells, J774A.1 (50,000 cells per well; American Type Culture Collection, TIB-67) that had been exposed to γ-irradiation (40 Gy) from a Shepherd irradiator. Three weeks after stimulation, culture supernatant was collected from each well, and levels of total IgM were measured using a previously described method [28]. We obtained 39 patient cultures (22 IGHV1-69 and 17 IGHV2/IGHV3) that produced similar levels of IgM. Of the 22 IGHV1-69 samples, 21 were U-CLL and 1 mutated CLL (M-CLL) while of the 17 IGHV2/IGHV3 samples, 9 were U-CLL and 8 M-CLL (Table S1). As negative controls, EBV-stimulated B cell cultures from PBMCs of 20 normal subjects were studied.

**Binding assays for screening and characterization of monoclonal antibody (mAb) specificity**

Culture supernatants or purified mAbs were assayed for reactivity to a panel of test antigens by ELISA [29], HIV-1 antigens included AT-2-inactivated HIV-1 virions ADA (clade B) [30], HIV-1 group M consensus envelope, ConS gp140 [31], deglycosylated JRFL gp140 [32], HIV-1 MN recombinant gp41 (Immunodiagnostics), a gp41 HR-1 region peptide, DLP70 (NNLRAEAAQQHLIQT VWGKQLEQRIKAVERYLKDO), an Env clade C HR-2 region peptide, MPER.656 (NEQELLELDKWASLWNWNTNWL), an Env clade B immunodominant region peptide, SP400 (RVLAVERYLDOQL LGIWGGSTKLICTTTAPWNASWSKSLNKL), and a Fab 8066 that had been exposed to γ-irradiation (40 Gy) from a Shepherd irradiator. Three weeks after stimulation, culture supernatant was collected from each well, and levels of total IgM were measured using a previously described method [28]. We obtained 39 patient cultures (22 IGHV1-69 and 17 IGHV2/IGHV3) that produced similar levels of IgM. Of the 22 IGHV1-69 samples, 21 were U-CLL and 1 mutated CLL (M-CLL) while of the 17 IGHV2/IGHV3 samples, 9 were U-CLL and 8 M-CLL (Table S1). As negative controls, EBV-stimulated B cell cultures from PBMCs of 20 normal subjects were studied.
Results

Reactivity of IGHV1-69 and non-IGHV1-69 B-CLL cells with HIV-1 and other antigens

To compare binding activities of B-CLL IgMs expressing IGHV1-69 vs. IGHV2/IGHV3 gene families, we stimulated PBMCs from 58 B-CLL patients (33 IGHV1-69 and 25 IGHV2/IGHV3) with EBV as described previously [28]. Three weeks after stimulation, we obtained 39 patient cultures (22 IGHV1-69 and 17 IGHV2/IGHV3) that produced similar levels of IgM. The mean IgM levels were 2.1 µg/ml (range, 0.13–10.1 µg/ml) and 2.1 µg/ml (range, 0.16–8.0 µg/ml) for IGHV1-69 and IGHV2/IGHV3 groups, respectively. As negative controls, EBV-stimulated B cell cultures from PBMCs of 20 normal subjects were studied. The mean IgM level of the control group was 6.7 µg/ml (range, 0.16–8.0 µg/ml).

The IGHV1-69 B-CLL PBMC culture supernatants were highly enriched for HIV-1 Env reactivity. Of 22 IGHV1-69 B-CLL patient samples, 6 (27.3%) reacted with HIV-1 Env; 5 (13.6%) reacted with ADA adriamycin-2 (AT-2)-maturated viros (1 (4.5%) with deglycosylated JRFL gp140, and 4 (18.2%) with one or more gp41 epitope peptides. In contrast, none of 17 IGHV2/IGHV3 patients reacted with deglycosylated JRFL gp140, and 4 (18.2%) with one or more gp41 epitope peptides. In contrast, none of 17 IGHV2/IGHV3 patients reacted with deglycosylated JRFL gp140, but not glycosylated gp140, indicating that Env glycosylation interfered with their reactivity. The CLL246 and CLL698 IgMs also reacted with each of 3 gp41 linear epitope peptides, DP107, MPR, 03, and SP400, indicating the polyreactive nature of the pentameric IgMs (Figure 1).

The 5 gp41-reactive B-CLLs expressed IGHV genes that were completely or nearly unmutated (Figure 2A). CLL246, CLL526, and CLL698 belong to the subset 7 of stereotypic rearrangements of BCRs described in B-CLL [14], and all but CLL821 used D region reading frame 2 that are enriched for hydrophobic amino acids (Table S1) [36]. Four of 5 gp41-reactive B-CLLs used IGHD-3 gene segment and 4 of 5 used IGJH6 gene segment. Further, all expressed long HCDR3s (21–23 aa) (Figure 2A). Of note, all but CLL246 used the F4-IGHV1-69 allelic variants.

We next expressed the 5 B-CLL mAb VDJH and VLJL genes as full-length IgG1 recombinant mAbs [29]. All 5 B-CLL recombinant IgGs bound to MN gp120 Env glycoprotein (Figure 1). We have previously demonstrated that deglycosylation of native Env exposes gp41 epitopes [32]. CLL246, CLL526, and CLL698 IgMs reacted with deglycosylated HIV-1 JRFL gp140 but not glycosylated gp140, indicating that Env glycosylation interfered with their reactivity. The CLL246 and CLL698 IgMs also reacted with each of 3 gp41 linear epitope peptides, DP107, MPR, 03, and SP400, indicating the polyreactive nature of the pentameric IgMs (Figure 1).

Figure 1. Reactivity of IgM paraproteins produced by B-CLL hetero-hybridomas and the corresponding recombinant IgG1 mAbs. Values are representative endpoint concentrations (in µg/ml) from at least two separate experiments. 1Deglycosylated JRFL gp140; 2HIV-1 gp41 HR-1 region peptide, DP107 sequence (NNLLRAIEAQQHLLQLTVWGIKQLQARILAVERYLKDQ); 3HIV-1 envelope clade C gp41 HR-2 region peptide, MPR.03 sequence (KKKNEQELLELDKWASLWNWFDITNWLWYIRKKK); 4HIV-1 BAL gp41 immunodominant region, SP400 sequence (RVLAVERYLRDQQLL-)

Figure 2A. Production and characterization of B-CLL mAbs

To test gp41 reactivity of B-CLL purified IgMs, we rescued 5 IGHV1-69 B-CLL mAbs as hetero-hybridoma IgM paraproteins; CLL246, CLL526, CLL698, CLL821, and CLL1324 (all U-CLL) as described previously [28]. A HIV-1-negative mAb (CCL1296; IGHSV6-7, 7.6% difference from the germline) was used as a negative control [28]. All 5 IGHV1-69 unmutated IgMs reacted with HIV-1 clade B MN gp41 recombinant protein while none reacted with HIV-1 MN gp120 Env glycoprotein (Figure 1). We have previously demonstrated that deglycosylation of native Env exposes gp41 epitopes [32]. CLL246, CLL526, and CLL698 IgMs reacted with deglycosylated HIV-1 JRFL gp140 but not glycosylated gp140, indicating that Env glycosylation interfered with their reactivity. The CLL246 and CLL698 IgMs also reacted with each of 3 gp41 linear epitope peptides, DP107, MPR, 03, and SP400, indicating the polyreactive nature of the pentameric IgMs (Figure 1).

The 5 gp41-reactive B-CLLs expressed IGHV genes that were completely or nearly unmutated (Figure 2A). CLL246, CLL526, and CLL698 belong to the subset 7 of stereotypic rearrangements of BCRs described in B-CLL [14], and all but CLL821 used D region reading frame 2 that are enriched for hydrophobic amino acids (Table S1) [36]. Four of 5 gp41-reactive B-CLLs used IGHD-3 gene segment and 4 of 5 used IGJH6 gene segment. Further, all expressed long HCDR3s (21–23 aa) (Figure 2A). Of note, all but CLL246 used the F4-IGHV1-69 allelic variants.

We next expressed the 5 B-CLL mAb VDJH and VLJL genes as full-length IgG1 recombinant mAbs [29]. All 5 B-CLL recombinant IgGs bound to MN gp41 (Figure 2B). Of these, CLL698 and CLL821 IgGs bound to the immunodominant region of HIV-1 clade B BAL gp41 ([RVLAVERYLRDQQLLGIWGCSKGLICTTAVPWNASWSNKSLKNE]) (Figure 2B). However, CLL246 and CLL698 IgGs did not bind to any other linear peptides tested including DP107, MPR, 03, MEP3656, and overlapping 15-mer MN gp41 linear peptides (data not shown). These results indicated that multivalent IgM antibodies with high avidity interactions could enhance low affinity interactions between the unmutated IgG antibodies and the linear peptides tested.

Gp41 antibodies that arise in HIV-1 infection frequently cross-react with intestinal commensal bacterial antigens and indeed have been postulated to derive from pre-transmission environment antigen-reactive antibodies from memory B cells [2]. Therefore, we tested reactivity of B-CLL mAbs with aerobic and anaerobic intestinal commensal bacterial whole-cell lysates using binding
We found all 5 IGHV1-69 unmutated IgMs reacted with aerobic and/or anaerobic intestinal commensal bacterial whole-cell lysates (Figure 1). The recombinant IgGs of CLL526 and CLL1324 also reacted with aerobic and/or anaerobic intestinal commensal bacterial whole-cell lysates (Figure 2B). Similarly, all 5 IGHV1-69 unmutated IgMs and their recombinant IgGs also reacted with HCV E2 protein (Figure 1 and Figure 2B). Two mAbs were chosen for cross-competition studies with HCV E2; recombinant E2 competitively inhibited the binding of CLL821 and CLL1324 IgGs to gp41 (Figure 3).

It has been proposed that B-CLL cells derive from autoreactive B cell precursors [6,37]. In this regard, 2 of 5 recombinant IgG mAbs (CLL698 and CLL1324) bound to double-stranded DNA but not to the other test autoantigens including SSA, SSB, Sm, RNP, ScI-70, Jo-1, centromere B, and histone (data not shown). In our indirect immunofluorescence staining assay, however, none of the IgM paraproteins or the recombinant IgG mAbs reacted with Hep-2 epithelial cells, and none showed rheumatoid factor activity (data not shown). In functional assays, none of the IgM or IgG B-CLL mAbs neutralized HIV-1 strains, SF162 (clade B), BG1168 (clade B), or MN (clade B) (Table S3) [2]. Similarly, none of the IgM mAbs inhibited syncytium formation by HIV-1 ADA (clade B) and MN nor captured HIV-1 virions, SF162 or BG1168 (Table S4 and Table S5). Moreover, none of the IgMs neutralized a HCV subtype 1a strain, HCVpp-H77 (Table S3) [38].

Comparison of gp41-reactive IGHV1-69 B-CLL mAbs with IGHV1-69 gp41 antibodies from HIV-infected patients

It has been previously reported that the IGHV1-69 B-CLL BCRs predominantly use IGHV1-69 allotypic variants with F54.
While the estimated global frequency of F at this position is 60% [20], we studied a series of gp41 antibodies isolated from acute or chronic HIV-1 infected subjects and found that of the 116 gp41 antibodies, 40.5% (47/116) were \( IGHV_{1-69} \) compared to 5.4% (32/595) of non-HIV-1-reactive antibodies isolated either from HIV patient plasma cells or from memory B cells (Table 1). Thus, while both B-CLL antibodies and HIV-1 gp41 antibodies are enriched in \( IGHV_{1-69} \) antibodies [39,40], B-CLL BCRs predominantly use \( L_54 \) while HIV-1 infection recruits predominantly \( L_54 \) allelic variant B cells to respond to HIV-1.

The HCDR3 sequences are the principal determinants of antibody-binding specificity in most antibodies [41]. Thus, we compared HCDR3 sequences of the 5 gp41-reactive \( IGHV_{1-69} \) B-CLLs with those of 47 gp41-reactive \( IGHV_{1-69} \) antibodies isolated from HIV-1-infected patients. The analysis revealed similar HCDR3 sequences due to common usages of \( IGHJ_6 \) and \( IGHD_3 \) gene segments that were preferentially used by gp41-reactive B-CLL mAbs. For example, the long HCDR3 sequences of mAbs Ab2757 (25 aa) and Ab6064 (23 aa) were remarkably similar (60% and 52% aa identity, respectively) to that of CLL1324 (Figure 4). However, \( IGHJ_4 \) was the most frequently used gene segment (32%) in the HIV-1 infection-derived \( IGHV_{1-69} \) gp41 antibodies in contrast to the infrequent use of \( IGHJ_4 \) by \( IGHV_{1-69} \) B-CLL (4%) [18]. In addition, \( IGHD_3-3 \), the most frequent D gene segment used by the gp41-reactive B-CLL mAbs was found in only 4% (2/47) of the HIV-1 infection-derived \( IGHV_{1-69} \) gp41 antibodies. The mean HCDR3 length of the HIV-1 infection-derived \( IGHV_{1-69} \) gp41 antibodies was significantly shorter than that of the gp41-reactive \( IGHV_{1-69} \) B-CLL antibodies (16.1 aa vs. 22 aa; Mann-Whitney test, p = 0.0041). Moreover, the sequence pattern cluster analysis of HCDR3s indicated that none of the HIV-1 infection-derived \( IGHV_{1-69} \) gp41 antibodies belonged to the known major B-CLL stereotype subsets [14]. These results indicate that the gp41-reactive \( IGHV_{1-69} \) CLL B cells have molecular features distinct from those found in most \( IGHV_{1-69} \) gp41 B cells during HIV-1 infection.

Virus binding activity of B-CLL and clinical outcomes

When we divided the B-CLL samples based on their binding activity to the test viral antigen preparations (Figure S1), we found that virus antigen-binding reactivity of B-CLL cultures correlated with B-CLL clinical course. The Kaplan-Meier plots of the analyses revealed that B-CLL cases with anti-viral reactivity correlated with poor clinical outcomes measured as time to first treatment (TFT) and overall survival of the patients (Figure 5). The median TFTs for virus-binding and non-virus binding groups were 37 mo and 86 mo, respectively (p = 0.011, Mantel-Cox test), and the median overall survival for virus-binding and non-virus binding groups were 131 mo and 177 mo, respectively (p < 0.0001, Mantel-Cox test). This was especially impressive when restricting the analysis to \( IGHV_{1-69} \) samples (Figure 5B and Figure 5D). The median overall survival for virus-binding and non-virus binding groups were 117 mo and indefinite, respectively (p = 0.012, Mantel-Cox test). Of note, all but one (CLL1011) \( IGHV_{1-69} \) gp41-69 samples were U-CLL and would therefore be expected to have poor clinical outcome [3]. However, the U-CLL \( IGHV_{1-69} \) samples could be segregated by virus binding activity, with the non-binders to viral antigens having good clinical outcome. These findings suggested that certain BCRs with innate anti-viral reactivity may be important factors in determining the outcome of the B-CLL clinical course.

Figure 3. Binding of recombinant B-CLL IgG1 mAbs to MN gp41 and HCV E2 proteins in surface plasmon resonance binding assays. MN gp41 (A) or HCV E2 (B) protein was captured on a sensor chip surface and test mAbs were injected over each of the test antigens. Test mAbs preincubated with either MN gp41 or HCV E2 proteins were injected over MN gp41 immobilized on a sensor chip surface (C). Data are expressed in response unit of binding to MN gp41. doi:10.1371/journal.pone.0090725.g003
In this paper, we have demonstrated that one third of IGHV1-69 B-CLL BCRs are polyreactive for infectious agent or commensal bacterial antigens (Figure S1 and Figure 1). B-CLL IgM reactivity with infectious agent antigens was significantly correlated with poor clinical outcomes (Figure 5). Moreover, there was a striking difference in IGHV1-69 allelic use by B-CLL versus HIV-1 IGHV1-69 antibodies. While IGHV1-69 B-CLL BCRs predominantly used F54 allelic variants, IGHV1-69 HIV-1 Env gp41 antibodies from HIV-1 infected patients predominantly used L54 (Table 1).

Liao et al. [2] have demonstrated that the initial blood plasma cell response in acute HIV-1 infection to gp41 is highly mutated and comprised of polyreactive gp41 antibodies that cross-react with intestinal commensal bacteria antigens. This work led to the hypothesis that the initial gp41 response to HIV-1 may be in part derived from commensal bacteria-activated memory B cells with BCRs that cross-react with Env gp41 and not from naive B cells [2]. Thus, HIV-1 Env in the context of HIV-1 infection induces a dominant Env gp41 antibody response that is polyreactive with host and intestinal commensal bacterial antigens [2]. The observation that IGHV1-69 B-CLL BCRs are similarly polyreactive and cross-react with intestinal commensal bacteria (Figure 1) raises the hypothesis that the B-CLL cell population is an expansion of members of the innate polyreactive B cell repertoire with reactivity to a number of infectious agent antigens including intestinal commensal bacteria. Hence, our results suggested that the initial response to gp41 in HIV-1 may derive from the same pool of B cells as B-CLL. However, it is striking that B-CLL B cells predominantly utilize F54 IGHV1-69 allelic variants while HIV-1 Env gp41 B cell BCRs from HIV-1 infection utilize L54 allelic variants (Table 1). Therefore, the B-CLL IGHV1-69 B cell usage of F54 allelic variants demonstrate that the initial response to gp41 in HIV-1 may not derive from the same pool of B cells as B-CLL. In fact, the B-CLL IGHV1-69 B cells may drive from an F54 allelic variant B cell pool that produces rare gp41 and hemagglutinin stem antibodies. It has been demonstrated that the F54 IGHV1-69 allelic variant B cells arise during early human fetal liver development [42]. They were found in a high proportion of B cells in the primary follicles of fetal spleen [43] and in the mantle zones of adult tonsil [44]. Thus, B-CLL B cells may derive from this mantle zone pool of polyreactive B cell precursors [18,45,46].

The 5 gp41-reactive unmutated B-CLL mAb clones had similar HCDR3 sequences due to common IGHV-D-J rearrangements, and as well, had long HCDR3s (21–23 aa) (Figure 2A). Three clones (CLL246, CLL526, and CLL698) belong to subset 7

1 All sequences are available in the IMGT and GenBank databases. 2 p < 0.0001 versus gp41-reactive IGHV1-69 antibodies isolated from HIV-1-infected subjects. Nd, not determined.

Figure 4. HCDR3 alignment of CLL1324 to gp41-reactive IGHV1-69 antibodies isolated from HIV-1-infected patients. The aa sequences of the HCDR3 regions of gp41-reactive IGHV1-69 antibodies isolated from HIV-1-infected patients were aligned to that of CLL1324. Each sequence was aligned independently to CLL1324 (pairwise alignment) using ClustalW and final adjustment was made manually. Gaps are indicated as dashes. The aa conserved between the sequences of CLL1324 and the other antibodies are highlighted in red. The number of aa shared with CLL1324 over the total aa is reported on the right for each antibody. Only the gp41 antibody sequences with HCDR3 % similarity ≥50% are reported. The CLL1296 IgM was used as a negative control. 1 Previously published sequence [51]; 2 CLL1296, HIV-1-negative control mAb; 3 IGHV1-69 antibodies with an F54 allelic variant. D RF, D gene reading frame; AAaa, aa in position 54.
Figure 5. B-CLL cases with anti-viral reactivity correlate with poor clinical outcomes. The Kaplan-Meier plots are shown for the time to first treatment (TFT, in months) in all samples (A) and IGHV1-69 samples (B). The p values for Mantel-Cox test in groups A and B are 0.011 and 0.217, respectively. The Kaplan-Meier plots are shown for overall patient survival (in months) in all samples (C) and IGHV1-69 samples (D). The p values for Mantel-Cox test in groups C and D are < 0.0001 and 0.012, respectively. Virus+ group represents B-CLL samples with ≥10 wells out of 20 wells tested showing a specific anti-viral reactivity (Figure S1). The results for virus-binding activity of 2 B-CLL samples (CLL821 and CLL1296) were obtained from the purified IgM paraproteins (Figure 1).

Supporting Information

Figure S1 Binding characteristics of B-CLL B cell cultures. To compare binding activities of B-CLL IgMs expressing IGHV1-69 vs. IGHV2/IGHV3 gene families, we stimulated PBMCs from B-CLL patients with EBV using the methods as previously described [28], and the cells were plated at 5,000 cells per well in total of 20 wells per patient sample. To profile binding characteristics of IgMs, we screened the culture supernatants in ELISA. HIV-1 Env gp41 linear epitope peptides included HR-1 region peptide, DP107 (NNLLRAIEAQQHLLQLTVWGIKQLQARI-LAVERYLKDQ); Env clade B HR-2 region peptide, MPER656 (NEQELLELDKWASLTNWFNITNWLV); and Env clade C

According to the major stereotyped BCR subset numbering based on a sequence pattern cluster analysis of B-CLL HCDR3s (Figure 2A) [14]. Unmutated B-CLL B cells with stereotypy give rise to the hypothesis that they are derived from a subset of B cells selected for ability to bind to bacterial and viral antigens, characteristics of B-1, transitional and MZ B cells [11]. It has been proposed that a small population of CD20+CD27+CD43+CD70- cells present in human umbilical cord and adult peripheral blood represent a B cell subset analogous to the murine B-1 subset [12], and human transitional and MZ B cells share traits that are similar to murine B-1 B cells, and collectively produce pre-formed antibodies to pathogens [47].

For both HIV-1 and HCV, we found no neutralizing antibodies among any of the B-CLL gp41 or HCV E2-reactive antibodies. Similarly, acute HIV-1 infection gp41 antibodies are non-neutralizing [1,2]. In contrast, the influenza-reactive non-mutated IGHV1-69 antibodies F10 and CR6260 neutralized a broad spectrum of influenza strains [21,24]. If IgM antibodies can coat infectious agent virions, they may impede virus migration across mucosal surfaces [48,49]. However, virus capture assays showed that none of gp41-reactive B-CLL mAbs captured test HIV-1 virions. Moreover, acute HIV-1 infection gp41 antibodies do not exert immune pressure via selecting escape mutants [1].

Finally, several studies have shown that unmutated B-CLL B cells, similar to natural or innate IgM antibodies, frequently express polyreactive antibodies that bind to autoantigens associated with apoptosis and oxidation as well as to components of the outer membrane of bacteria [37,50]. Of note, it has been demonstrated that human B-1-like cells (CD20+CD27+CD43+CD70-) displayed a skewed BCR repertoire as indicated by preferential expression of anti-phosphorylcholine and anti-DNA specificities [12]. Our findings that unmutated B-CLL cell gp41 reactivity is selective for the F54 IGHV1-69 gene segment and has characteristics of B-1-like, transitional and MZ B cell derived antibodies strongly suggest that B-CLL IGHV1-69 gp41 antibodies derive from a restricted B cell pool that also produces rare HIV-1 gp41 and influenza hemagglutinin stem antibodies.
