Objective: The aim of this study was to clarify the role of pancreatic surgery during the COVID-19 pandemic to optimize patients’ and clinicians’ safety and safeguard health care capacity.

Summary Background Data: The COVID-19 pandemic heavily impacts health care systems worldwide. Cancer patients appear to have an increased risk for adverse events when infected by COVID-19, but the inability to receive oncological care seems may be an even larger threat, particularly in case of pancreatic cancer.

Methods: An online survey was submitted to all members of seven international pancreatic associations and study groups, investigating the impact of the COVID-19 pandemic on pancreatic surgery using 21 statements (April, 2020). Consensus was defined as >80% agreement among respondents and moderate agreement as 60% to 80% agreement.

Results: A total of 337 respondents from 267 centers and 37 countries spanning 5 continents completed the survey. Most respondents were surgeons (n = 302, 89.6%) and working in an academic center (n = 286, 84.9%). The majority of centers (n = 166, 62.2%) performed less pancreatic surgery because of the COVID-19 pandemic, reducing the weekly pancreatic resection rate from 3 (interquartile range (IQR) 2–5) to 1 (IQR 0–2) (P < 0.001). Most centers screened for COVID-19 before pancreatic surgery (n = 233, 87.3%). Consensus was reached on 13 statements and 5 statements achieved moderate agreement.

Conclusions: This global survey elucidates the role of pancreatic surgery during the COVID-19 pandemic, regarding patient selection for the surgical and oncological treatment of pancreatic diseases to support clinical decision-making and creating a starting point for further discussion.

Keywords: ampullary adenocarcinoma, CA19-9, chronic pancreatitis, COVID-19, distal bile duct cancer, duodenal adenocarcinoma, hospital volume, intensive care unit, intraductal papillary mucinous neoplasms, minimally invasive surgery, neoadjuvant treatment, pancreatic cancer, pancreatic necrosis, pancreatic neuroendocrine tumor, pancreatic surgery, pandemic, respectability, SARS-CoV-2

(Am Surg 2020;272:87–e93)
Therefore, this international survey study aimed to clarify the role of pancreatic surgery during the COVID-19 pandemic through 21 statements, aiming to optimize safety for patients and clinicians, and safeguard health care.

**METHODS**

**Survey**

An online survey was designed and submitted to all members of 7 international pancreatic associations and study groups: the Pancreas Club, European Pancreatic Club, Chinese Pancreatic Surgery Association, European Consortium on Minimally Invasive Pancreatic Surgery, Study Group of Preoperative Therapy for Pancreatic Cancer, Study Group of Pancreatic Ductal Adenocarcinoma with Peritoneal Metastasis, and International Study Group on Cystic Tumors of the Pancreas using Google Forms (Google LLC, Menlo Park CA). Both surgeons and nonsurgeons (eg, gastroenterologists and medical oncologists) were asked to participate in this survey to balance the discussion.

The survey consisted of 36 questions on baseline characteristics, the local impact of the COVID-19 pandemic on pancreatic surgery (ie, number of pancreatic resections, triage, and screening), and 21 statements about the role of pancreatic surgery in the current era of the COVID-19 pandemic. Each statement had to be appraised using 3 options: agree, disagree, and uncertain. See Text – Supplemental Digital Content 1, http://links.lww.com/SLA/C199 for the survey.

The survey was conducted in the first 2 weeks of April 2020. Nonrespondents were reminded twice because of the rapid developments in the current COVID-19 crisis and need for novel policy development a relatively short time window was used. Respondents were asked to register their name and institution to prevent overlap of members between the above-mentioned associations. The response rate could not be calculated since associations submitted the survey themselves. All study procedures were reviewed and approved by the Colorado Multiple Institutional Review Board (COMIRB) (protocol #20-0843) at the University of Colorado.

**Definitions**

Pancreatic ductal adenocarcinoma, bile duct cancer, duodenal and ampullary adenocarcinomas, intraduodenal papillary mucinous neoplasms (IPMNs), and pancreatic neuroendocrine tumors (pNETs) were defined in accordance to the WHO definitions.8,9 A hospital was defined as a high-volume pancreatic center when performing ≥20 pancreaticoduodenectomies annually.10 Consensus was defined as >80% agreement among respondents and moderate agreement was defined as 60% to 80% agreement among them.

**Statistical Analysis**

Variables were processed and analyzed using IBM SPSS Statistics for Microsoft Windows version 26 (IBM Corp., Orchard Road Armonk, NY). Data were reported as number with percentage or as median with interquartile range (IQR). The weekly volume of pancreatic resections before and during the COVID-19 pandemic was compared, using the Wilcoxon signed-rank test for non-normally distributed variables. Sensitivity analyses were performed to investigate the influence of specialty, the type of center, and continent. Statistical significance was considered as 2-tailed P value <0.050.

**RESULTS**

**Participants**

A total of 337 respondents from 267 centers and 37 countries spanning 5 continents completed the online survey. See Figure 1 for the number of responses per country. Most respondents were working in an academic center (n = 286, 84.9%) and the majority of participants were surgeons (n = 302, 89.6%). See Table 1 for the characteristics of the respondents. The median annual hospital and individual surgeon volume of pancreatic resections were 75 (IQR 46–140) and 35 (IQR 20–60), respectively.

**Impact of COVID-19 Pandemic**

During the peak of the COVID-19 pandemic, 67.8% (n = 181) of centers prioritized between different types of pancreatic resections. Before pancreatic surgery, most centers screened patients for COVID-19 (n = 233, 87.3%), whereas some centers did not (n = 31, 11.6%). See Table 2 for the preoperative COVID-19 screening strategy. The majority of centers (n = 166, 62.2%) performed less pancreatic surgery as consequence of the COVID-19 pandemic. From these centers, the weekly numbers of pancreatic resections decreased from 3 (IQR 2–5) to 1 (IQR 0–2) (P < 0.001). In addition, 30.7% (n = 51) of responding centers performed no pancreatic surgery at all.

**Statements**

Consensus was reached on 13 from the 21 statements (62%) and moderate agreement was achieved on 5 statements (24%). The remaining 3 statements had an agreement <60%. See Tables 3 to 5 for the statement outcomes.

**Sensitivity Analyses**

The statement outcomes barely changed after excluding the nonacademic centers, without any shifts in the 3 categories of agreement. Exclusion of nonsurgeons lead to the movement of statement 5—regarding the prioritization of patients with limited/without comorbidity for surgery to increase the ICU capacity—to the lowest group of agreement (61.1%–59.9%).

Analyzing the outcomes of Europe (n = 149, 44.2%), Asia (n = 115, 34.1%), and the Americas (ie, North and South America) (n = 71, 21.1%) separately demonstrated some changes in agreement. The European respondents did not reach consensus on statement 3 (76.5% agreement) regarding the prioritization of patients based on objective prognostic factors and comorbidity. In contrast to the overall outcomes, Asia achieved consensus on statement 4 (81.7% agreement) to prioritize each patient for pancreatic surgery, based on prognostic factors. Whereas Europe agreed on the importance of high-volume centers to operate high-risk patients during the COVID-19 pandemic (87.9% agreement), both Asia (75.7% agreement) and the Americas (76.1% agreement) did not reach consensus on statement 16. The recommendation for preoperative screening on COVID-19 (statement 19) reached solely consensus (84.5% agreement) in the Americas. See Table—Supplemental Digital Content 2–4, http://links.lww.com/SLA/C200, http://links.lww.com/SLA/C201, http://links.lww.com/SLA/ C202, for the statement outcomes of Europe, Asia, and the Americas separately.

**DISCUSSION**

This global survey study aimed to clarify the role of pancreatic surgery during the COVID-19 pandemic through 21 statements. The statements regarding patient selection for the oncological and surgical treatment of pancreatic diseases could assist clinicians in their clinical decision-making and create a starting point for further discussion.

A literature review was performed (see Table—Supplemental Digital Content 5, http://links.lww.com/SLA/C203 for the search strategy) to evaluate the current evidence about pancreatic surgery during the COVID-19 pandemic. Kutikov et al6 concluded...
that (suspected) pancreatic cancer does not allow any treatment delay and, therefore, requires immediate surgical treatment, but did not address (neo)adjuvant therapy. Patients with both COVID-19 and cancer or treated with chemotherapy/surgery in the last months seem to be at risk for severe events (ie, ICU admission requiring invasive ventilation, or death) in comparison to COVID-19 patients without cancer, according to a Chinese series.4 Therefore, Liang et al4 advised to postpone adjuvant chemotherapy or elective surgery for stable cancer in endemic areas. In contrast, Ueda et al7 emphasized that adjuvant therapy with curative intent for solid tumors should proceed, and surgery needs prioritization as well. This latter statement is supported by the Society of Surgical Oncology (SSO), stating that hepatopancreato-biliary malignancies are typically aggressive and, therefore, should not be considered as “elective” care.11 In addition, the Society of American Gastrointestinal and Endoscopic Surgeons (SAGES) and the European Association of Endoscopic Surgery recommended to postpone all elective surgery with exception of surgical care for life threatening diseases such as progressive malignancies.12 Nevertheless, the limited evidence regarding the role of pancreatic surgery in the era of the COVID-19 pandemic underlines the need for an international survey with clear statements, aiming to guide

FIGURE 1. Number of responses per country.
TABLE 1. Characteristics of Respondents

| Age, y* | 49 (41–55) |
| Profession, n (%) |  
| Surgeon | 302 (89.6) |
| Gastroenterologist | 20 (5.9) |
| Oncologist | 4 (1.2) |
| Surgical resident | 5 (1.5) |
| Others | 6 (1.8) |
| Type of center, n (%) |  
| Academic center | 286 (84.9) |
| Nonacademic center | 51 (15.1) |
| Experience as attending specialist, y* | 18 (9–25) |
| Scope of current clinical practice, n (%) |  
| Hepato-pancreato-biliary surgery | 177 (52.5) |
| Pancreatic surgery | 62 (18.4) |
| Surgical oncology | 32 (9.5) |
| General surgery | 23 (6.8) |
| Gastrointestinal surgery | 14 (4.2) |
| Gastroenterology | 17 (5.0) |
| Medical oncology | 5 (1.5) |
| Others | 7 (2.1) |

*Median (interquartile range); n, number of respondents.

Table on clinical practice, scope of current clinical practice, and type of center.

Clinicians in their clinical decision-making. The statement outcomes of the present international expert survey revealed several consensus statements as well as statements that need further discussion.

TABLE 2. Preoperative Screening for COVID-19

| Screening, n (%) | 233 (87.3) |
| Including symptoms | 184 (68.9) |
| Including CT chest | 104 (39.0) |
| Including PCR | 113 (42.3) |
| Including symptoms + CT chest + PCR | 55 (20.6) |
| No screening, n (%) | 31 (11.6) |
| Missing data, n (%) | 3 (1.1) |

CT indicates computer tomography; n, number of centers; PCR, polymerase chain reaction.

Triage

Patients with increased risk for postoperative respiratory failure should not be prioritized for surgery in absence of full hospital capacity, according to consensus statement 6. In contrast, only 61% agreement was reached on statement 5 comprising the proposition for surgery only for patients with limited/without comorbidity to minimize the use of ICU capacity for COVID-19 patients. The American College of Surgeons (ACS) underlined consensus statement 6, stating that “For elective cases with a high likelihood of postoperative ICU or respirator utilization, it will be more imperative that the risk of delay to the individual patient is balanced against the imminent availability of these resources for patients with COVID-19.”

The aggressive biology of pancreatic cancer justifies elective...
pancreatic surgery as indispensable care and, therefore, should not be exclusively performed for very low risk patients as prevention to overload hospital resources (see the section “Pancreatic cancer” below for further explanation and recommendations). This could be the rationale for a low agreement on statement 5. The ACS emphasized that continuation of “elective” surgical care has to be frequently evaluated and adapted if needed, based on the impact of the COVID-19 pandemic on local resources. A reliable and objective model is needed to stratify patients and guide prioritization in accordance to hospital capabilities, such as the recently developed respiratory failure risk score for elective abdominal and vascular surgery, that identified pancreatic surgery among others as an independent risk factor for postoperative respiratory failure. 

Screening and Protection for COVID-19

Before pancreatic surgery, most centers represented in this survey screened their patients for symptoms of COVID-19. No consensus was reached to recommend COVID-19 preoperative testing/screening (statement 19). This seems a plea to obligate some type of screening, but not necessarily with PCR and/or computer tomography chest, particularly considering SAGES. SAGES underlines that recommendation of the Corona Virus Global Surgical Collaborative to perform some type of screening test for all patients (even if asymptomatic and without risk factors) who will undergo a surgical or interventional endoscopic procedure in institutions seeing high volumes of COVID-19 patients. In addition, ACS advised to wait for the results of COVID-19 testing in patients who may be infected.

Based on consensus, patients who will undergo pancreatic surgery should be informed about the following additional risks: COVID-19 infection during hospitalization, possible nonoptimal postoperative management (ie, shortage of ICU beds), increased risk of COVID-19 related mortality due to surgery or the cancer condition (statement 17). Furthermore, this survey convincingly recommends that operating room (OR) personnel have to wear adequate protective features during surgery, considering their increased risk for COVID-19 infection during surgical procedures (statement 20).

**Pancreatic Cancer**

According to the consensus statements for patients with pancreatic cancer, each patient should be operated after completing neoadjuvant therapy (statement 1), as is also advised by the SSO. However, patients should be prioritized based on objective prognostic factors and comorbidities in case of limited resources. If surgery is postponed, patients should continue with neoadjuvant therapy (statement 3), but neoadjuvant therapy should not be used to select each patient with nonmetastatic pancreatic cancer for surgery (statement 2). Subsequently, patients with postponed surgery need to be evaluated as soon as possible for surgery when resources are available again (statement 7). Oba et al recently described the value of a new nomogram for pancreatic cancer, estimating patients’ predicted survival based on preoperative factors and confirmed the prognostic power of known predictive factors. These models could be used for prioritization of surgery for pancreatic cancer in case of limited resources. However, no consensus was reached on statement 4 and 5 to prioritize each pancreatic cancer patient on comorbidity and objective pancreas cancer-related prognostic factors, considering the life threatening nature of pancreatic cancer. Nevertheless, statement 18 prioritization of COVID-19 patients with a better prognosis over pancreatic cancer patients adhering to the process of triage for hospital resources and ICU beds—did not reach 60% agreement.

<table>
<thead>
<tr>
<th>TABLE 4. Statement Outcomes—Moderate Agreement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement</td>
</tr>
<tr>
<td>4) Objective prognostic factors (eg, levels of CA19–9, reduction of levels of CA19–9 after NAT, treatment in academic centers) should be used to predict the prognosis for every patient with pancreatic cancer so that prioritization can be made.</td>
</tr>
<tr>
<td>5) To prevent ICU bed overload and maximize the availability of ICU bed for COVID-19 patients, surgery should be proposed to patients with limited/without comorbidity.</td>
</tr>
<tr>
<td>8) The recommendation for patients with distal bile duct cancer that require PD can be equivalent to those for pancreatic cancer.</td>
</tr>
<tr>
<td>19) COVID-19 preoperative testing/screening (eg, chest CT, PCR) is recommended, but not mandatory. The tests will be done according to the policy of the hospital.</td>
</tr>
<tr>
<td>21) Minimally invasive techniques can be performed in accordance to the risk reducing procedural advice of Zheng et al since the current evidence regarding the increased risk of COVID-19 spreading in the OR by minimally invasive techniques is limited.</td>
</tr>
</tbody>
</table>

**TABLE 5. Statement Outcomes—Low Agreement**

| Statement | Agree | Disagree | Uncertain |
| 2) Every patient affected by nonmetastatic pancreatic cancer, independent of the stage of disease (primary resectable, borderline resectable, locally advanced) should receive NAT before surgery, so that the best candidates can be selected and for surgical resection and resources allocation can be rationalized. | 59.6% | 26.4% | 13.9% |
| 15) In case of duodenal and ampullary cancers, surgery can be postponed or neoadjuvant chemotherapy could be considered, unless patients have life threatening risks (ie, bleeding, bowel obstruction). | 47.2% | 40.4% | 12.5% |
| 18) Adhering to the process of triage, hospital resources and ICU beds should be prioritized for COVID-19 patients with better prognosis over patients who undergo surgery for pancreatic cancer. | 56.1% | 22.6% | 21.4% |

Low agreement was defined as <60% agreement among respondents. NAT indicates neoadjuvant therapy.
Periampullary Malignancies (Without Pancreatic Cancer)

Statement 8 proposed to manage distal bile duct cancer as equivalent to pancreatic cancer. However, the lack of consensus (71%) implies that surgery might have slightly less priority in comparison to pancreatic cancer since 23% of respondents disagreed on the other hand. The SSO stated that extrahepatic bile duct cancer and ampullary and duodenal adenocarcinomas should be operated as soon as feasible, regardless of the presence of symptoms. However, a high disagreement rate (40%) was reached on statement 15 for postponing surgery or giving neoadjuvant chemotherapy for duodenal and ampullary cancers in absence of life threatening risks (ie, bleeding, bowel obstruction). Since evidence is limited about the efficacy of neoadjuvant chemotherapy for these cancers so far and could not be deemed to stable diseases, many physicians might thought these should be resected as indicated.

Benign or Premalignant Pancreatic Diseases

Consensus was reached to postpone surgery for benign and premalignant pancreatic diseases, including IPMNs, pNETs, chronic pancreatitis, and infected pancreatic necrosis. Exceptions comprise life threatening complications of chronic pancreatitis or infected pancreatic necrosis, symptomatic pNETs without effective alternative treatment options, or pNETs or IPMNs with suspicion for malignancy (statements 9–14).

High-Volume Care

Volume–outcome relationships in pancreatic surgery are well established with shorter hospital stay and lower mortality in high-volume centers. Pancreatic surgery in high-risk patients should not be performed in low-volume centers during the COVID-19 pandemic, aiming to reduce the risk of long hospital stay and major complications requiring ICU care (statement 16). Remarkably, the sensitivity analysis revealed that only Europe reached consensus in contrast to Asia and the Americas.

Minimally Invasive Surgery

Statement 21 demonstrated the limited evidence regarding the safety of minimally invasive surgery, illustrated by the substantial percentage of respondents who agreed (65%) or were uncertain (24%). Although previous research has shown that laparoscopy can lead to aerosolization of blood borne viruses, SAGES advised to continue to perform minimally invasive surgery in accordance to their risk reducing procedural advice. SAGES will monitor emerging evidence considering the limited evidence about the relative risk of COVID-19 spreading in the OR by minimally invasive surgery in comparison to conventional open surgery. The ACS mentioned that aerosol-generating procedures increase the risk for OR personnel and may not be avoidable, but confirmed the insufficiency of evidence to recommend or discourage minimally invasive surgery. Meanwhile, SAGES underlined the proven benefits of minimally invasive surgery to reduce postoperative morbidity and hospital stay and, therefore, should be strongly considered in these patients.

Strengths and Limitations

The strength of this survey is the global range of respondents, representing a wide range of countries and continents. However, the results should be interpreted in light of some limitations. First, only 10.4% nonsurgeons (eg, medical oncologists and gastroenterologists) participated in this survey, which could possibly outbalance the discussion regarding the oncological treatment of pancreatic diseases. Second, a relatively small group of 8 countries was responsible for the majority of survey participants (76.6%). Third, only a minority of participants represented the nonacademic centers.

CONCLUSIONS

In summary, this survey reached consensus on the majority of statements for the role of pancreatic surgery during the COVID-19 pandemic to optimize safety for patients and clinicians and safeguard health care capacity by prioritizing only the most relevant care for patients with non-COVID-19 pancreatic diseases.

The statements may be updated, based on more solid evidence about the management of periampullary cancers (ie distal bile duct cancer, and duodenal and ampullary adenocarcinomas), preoperative screening modalities, and the safety of minimally invasive surgery in relation to the COVID-19 pandemic.

ACKNOWLEDGMENT

The authors thank all participating members and the leadership of the Pancreas Club, European Pancreatic Club, Chinese Pancreatic Surgery Association, European Consortium on Minimally Invasive Pancreatic Surgery, Study Group of Preoperative Therapy for Pancreatic Cancer, Study Group of Pancreatic Ductal Adenocarcinoma with Peritoneal Metastasis, and International Study Group on Cystic Tumors of the Pancreas for supporting this survey.
